

# SOFOG3D – UK Met Office update on deterministic model comparison with observations

*Jenna Thornton, Paul Field, Jeremy Price, Anne McCabe, Steve Derbyshire, Adrian Lock, Bernie Claxton*

*7<sup>th</sup> June 2022*

- (1) Overview of model setup and methodology
- (2) Categorized list of case studies
  - focusing in this presentation mainly on radiation fog cases
  - but we do also have stratus fog cases and null cases
- (3) Sensitivity tests
  - Output from different model configurations
  - Effect of changing setup parameters
- (4) VERA output – a different visibility scheme
- (5) Conclusions and Further work

## Methodology

comparisons and tests

- We use measurements primarily from **Le Couye**
  - Plus some comparisons with the nearby (slightly more open) **Jachere** site
- We categorize periods as: radiation fog/no fog/stratus fog
- We evaluate the standard model against these measurements for visibility and other relevant parameters
- We test sensitivity to various existing model options, including cloud, aerosol and surface options
- We also compare with a new stochastic diagnostic visibility scheme (VERA)

- UM deterministic model ran initially @ 100m, 300m, and 1.5km resolutions
- Previous presentation discussed these runs [UKMO model vs obs 20210330](#)
- **Only results from 1.5km horizontal resolution shown in this presentation**
  
- Vertical grid: standard 70 model levels
  - Level 1 corresponds to 5m
  - Additional diagnostic outputs at 1.5m: visibility, temperature, RH
  
- Run (for selected dates) from 1200UTC on day x until 2300UTC on x+1

# Categorization of different types of events

## Observed stratus fog events

- **5<sup>th</sup> to 6<sup>th</sup> January 2020**
- **8<sup>th</sup> to 9<sup>th</sup> February 2020**
- **7<sup>th</sup> to 8<sup>th</sup> March 2020**

## Null case (no observed fog)

- **11<sup>th</sup> to 12<sup>th</sup> January 2020**

## Observed radiation fog events

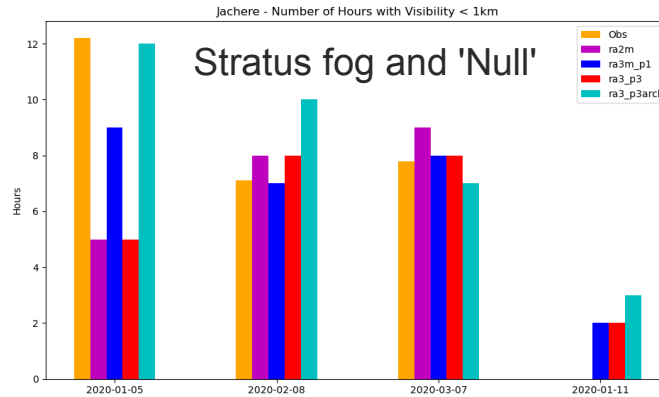

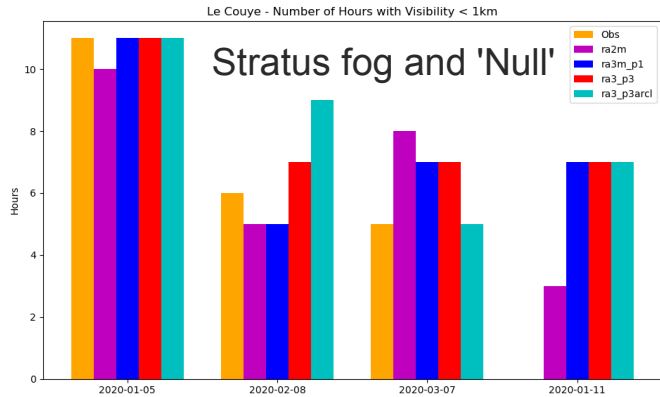

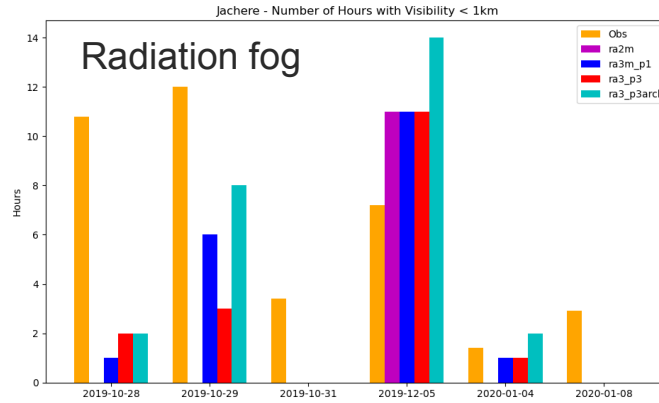

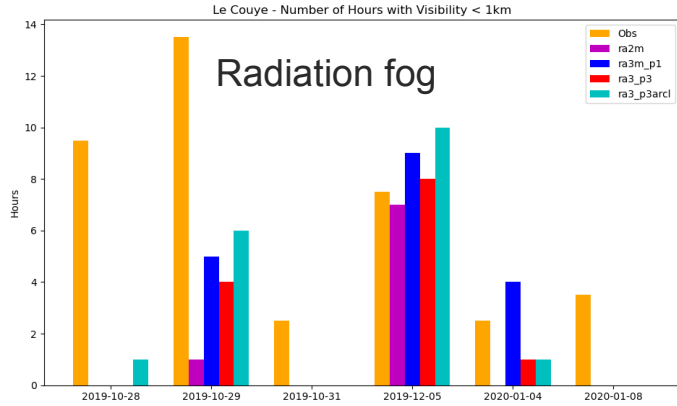

- **28<sup>th</sup> to 29<sup>th</sup> October 2019**
- **29<sup>th</sup> to 30<sup>th</sup> October 2019**
- **31<sup>st</sup> October to 1<sup>st</sup> November 2019**
- **5<sup>th</sup> to 6<sup>th</sup> December 2019**
- **4<sup>th</sup> to 5<sup>th</sup> January 2020**
- **8<sup>th</sup> to 9<sup>th</sup> January 2020**

## Sensitivity test one – using different model configurations

1. Current operational configuration
2. Same as 1 but using a **bimodal-cloud scheme**
3. Same as 2 but using a **double-moment microphysics scheme (CASIM)**
4. Same as 3 but changing the **aerosol climatology (aerosol more interactive)**

*Links to further info given on final slide*

- Operational
- With bi-modal cloud scheme
- With CASIM microphysics & bi-modal cloud scheme
- With CASIM microphysics & bi-modal cloud scheme & aerosol climatology

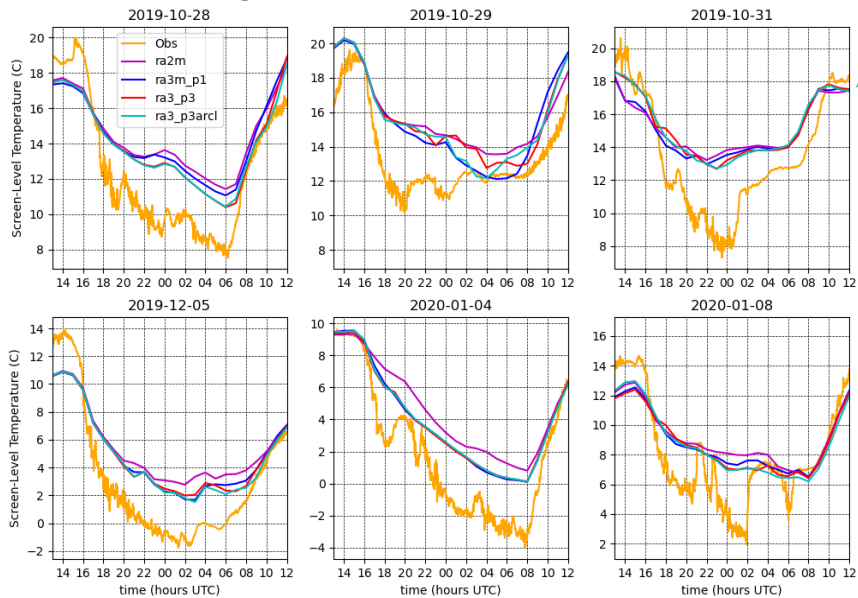

- More fog when bi-modal cloud scheme and CASIM are used
- Stratus fog better predicted than radiation fog
- Fog formed during 'null' case

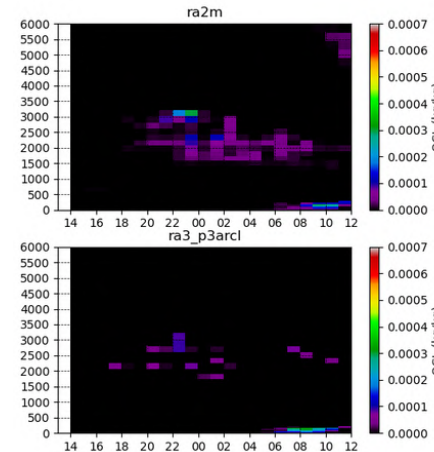

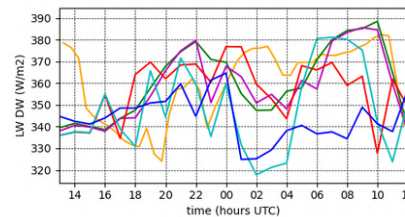

# Radiation fog

Le Couye

2019-10-29

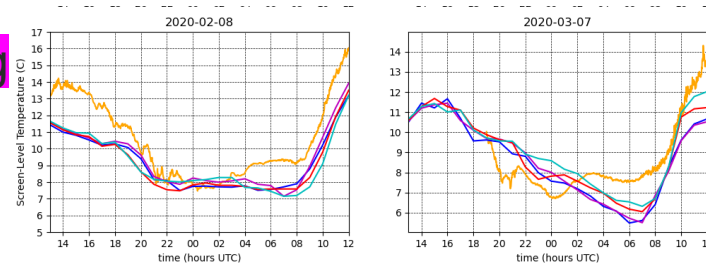

Screen-level temperatures drop lower when CASIM and bi-modal cloud schemes are used, probably due to **less cloud**.

# Stratus fog

Screen temperatures generally too high during radiation fog cases...

.. but not necessarily in Stratus fog

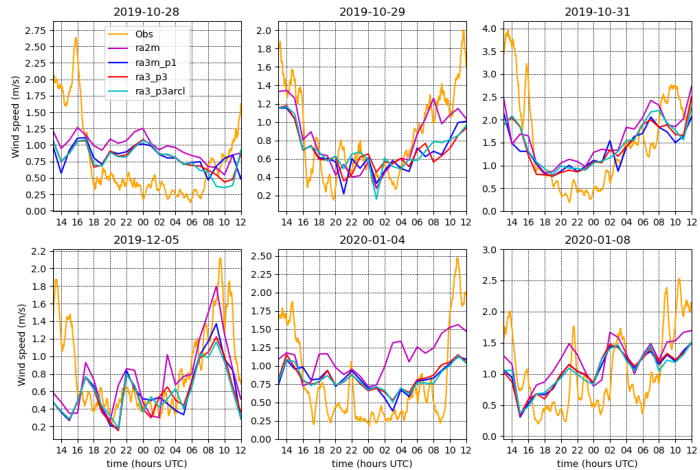

Output from different model configurations

Additionally...  
wind speed  
and WW  
generally too  
high

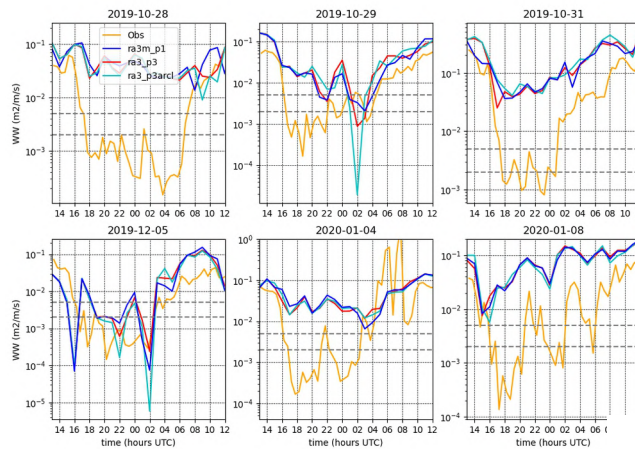

## Wind speeds 2m

Le Couye

## WW

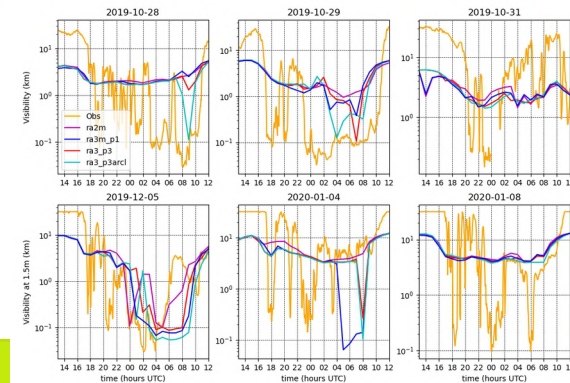

Le Couye

Model wind speed and WW closest to observations  
on 2019-10-29 and 2019-12-05 – fog also predicted  
for these dates

## Visibility

Le Couye

Output from different model configurations

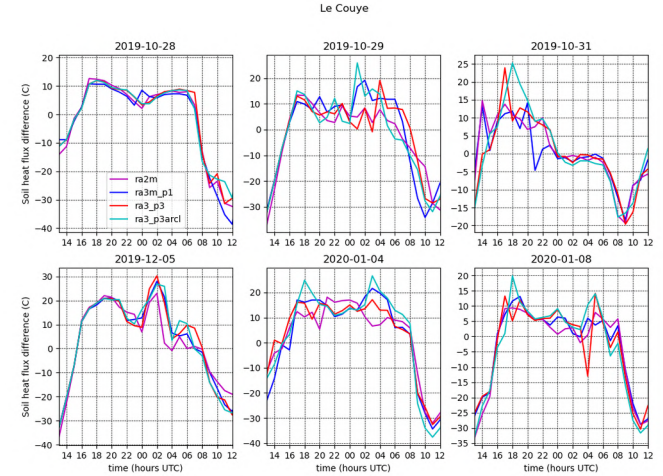

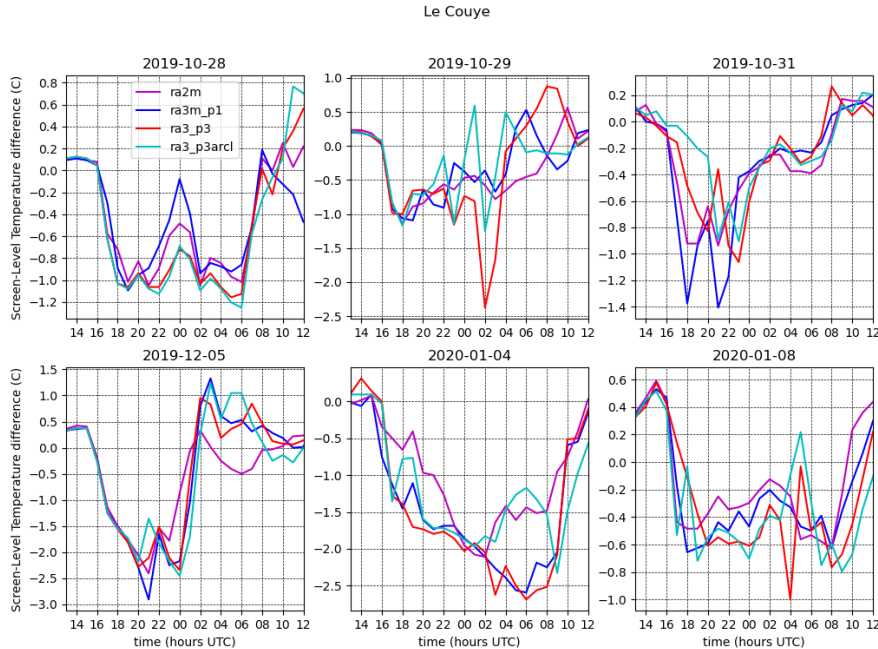

Sensitivity test two – changing set-up parameters

Aim: Reduce skin and near-surface temperatures

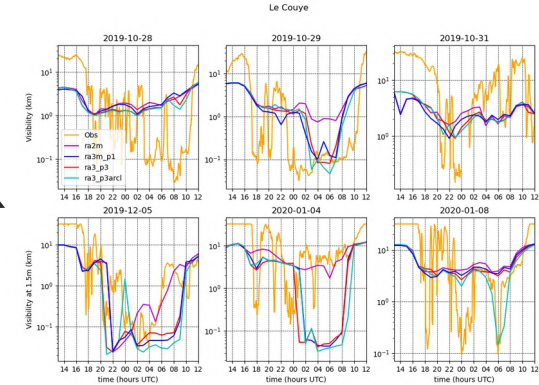

How: Effectively modifying bare soil fraction to limit turbulent exchange between atmosphere and surface

## (1) Soil heat flux – less from soil to surface

## (2) Temp reductions

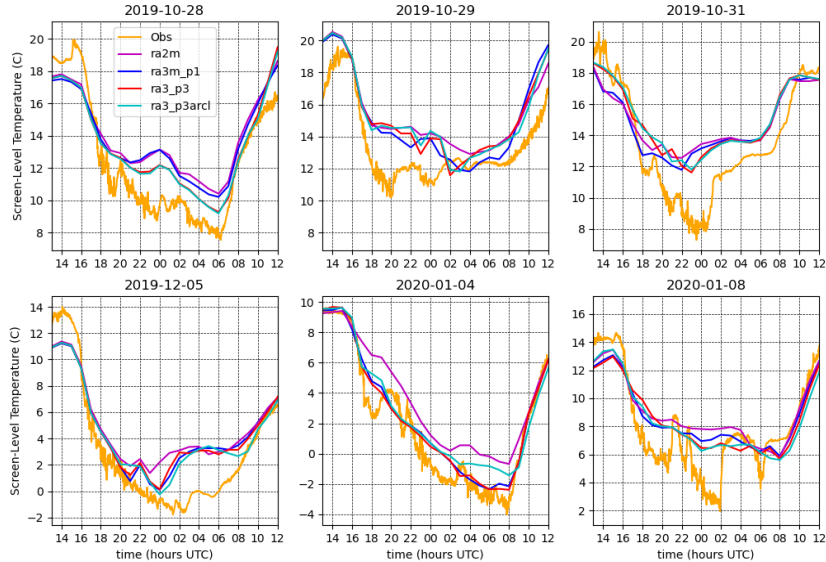

## (3) More fog formed

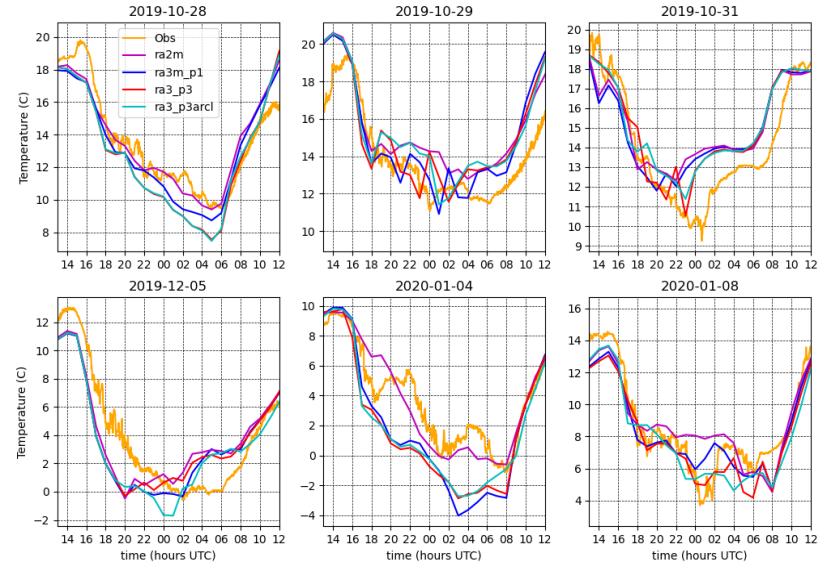

**But** model temperatures still generally too high at **Le Couye**

### Le Couye – after change in set-up

**However** temperatures more comparable at **Jachere**  
– Jachere temperature reductions up to double those at Le Couye

### Jachere – after change in set-up

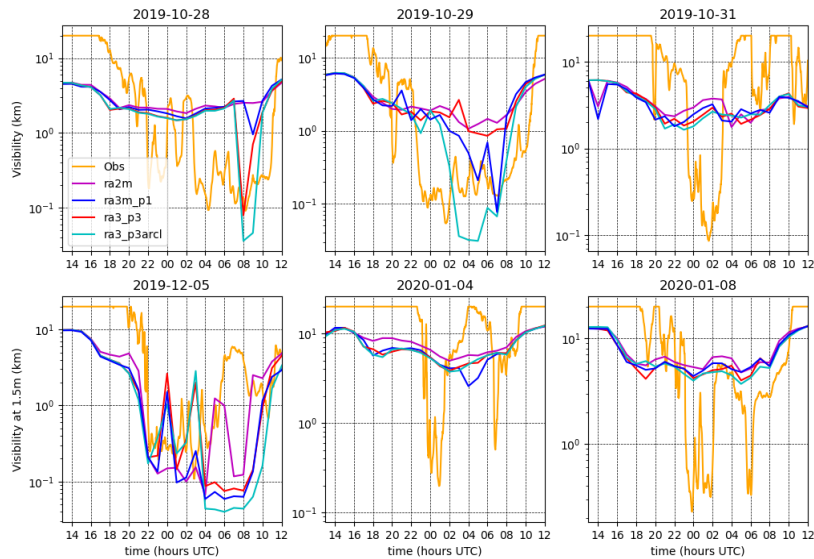

Warmer at Le Couye – due to model averaging over the grid box whereas obs are local?

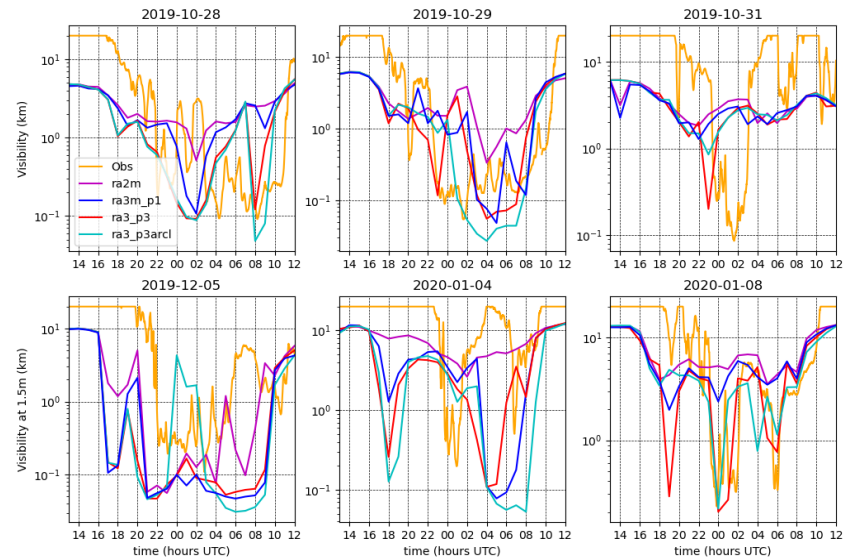

IR camera at UKMO site – surrounding trees warmer than surface

... with reduction in screen-level temperature, model now formed fog during each radiation fog case at **Jachere**

Jachere – before change in set-up

Jachere – after change in set-up

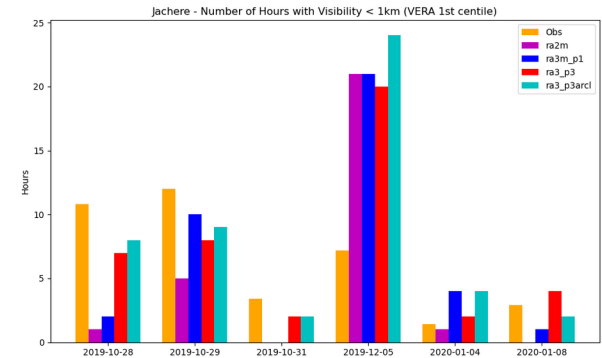

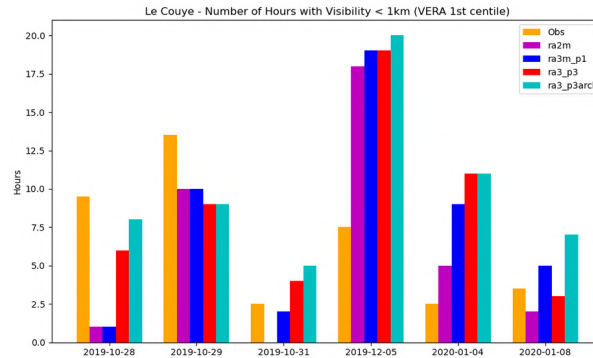

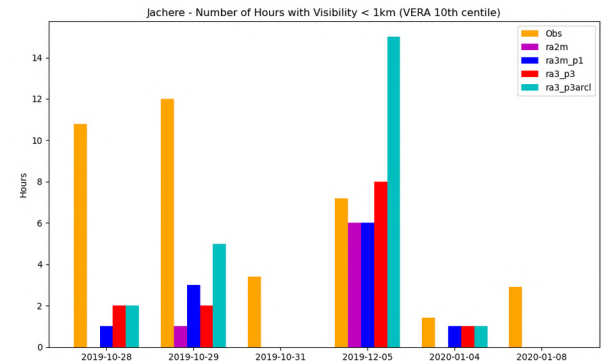

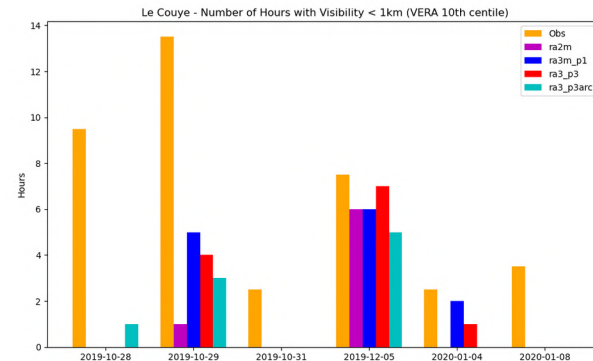

## Very briefly.... VERA is a new visibility scheme (B Claxton)

- VERA uses polydisperse aerosol particles (lognormal size distribution and triangular hygroscopy distribution)
- Synthetic noise added to VERA to generate a set of possible visibilities...
- Outputs: probabilities of vis below specific thresholds, and centiles of these.

## Lowest 1% of visibility outputs

## Lowest 10% of visibility outputs

- Met Office UM has been run using more sophisticated visibility, cloud, and microphysics schemes as tests
- Standard model (control) tends to under-predict **radiation fog** events – but when a bi-modal cloud scheme and/or a double-moment microphysics scheme (CASIM) are implemented:
  - Fog is more willing to form
  - Skin and near-surface temperatures can drop lower
  - Low/mid level cloud (higher than 200m) is less persistent
- Model doesn't cool enough in the late afternoon/early evening before an observed radiation fog event
  - Forcing a cooler surface T leads to enhanced fog formation
  - Even after this forcing, the surface temperature is still too high in the model output during evenings that were followed by observed radiation fog events at Le Couye
- Model vertical velocity variance WW looks too high (certainly at **Le Couye**)

### Future work

- Further investigation into temperature bias based on tile temperatures rather than grid-box values.
- Investigate alternative ways to reduce skin and near-surface temperature
- More detailed look at the **Stratus fog** cases

Acknowledgement: Merci beaucoup to all who have been involved in the collection and provision of data at the Jachere site!

## Any Questions?

# Met Office Sensitivity test modifying bare soil fraction

- The fraction bare soil exposed to the atmosphere on vegetated tiles is related to the LAI as:
- Here we increase  $k_{ext}$  from 1 to 4(?)
- Reducing  $F_{soil}$  weakens the thermal coupling between the soil and atmosphere

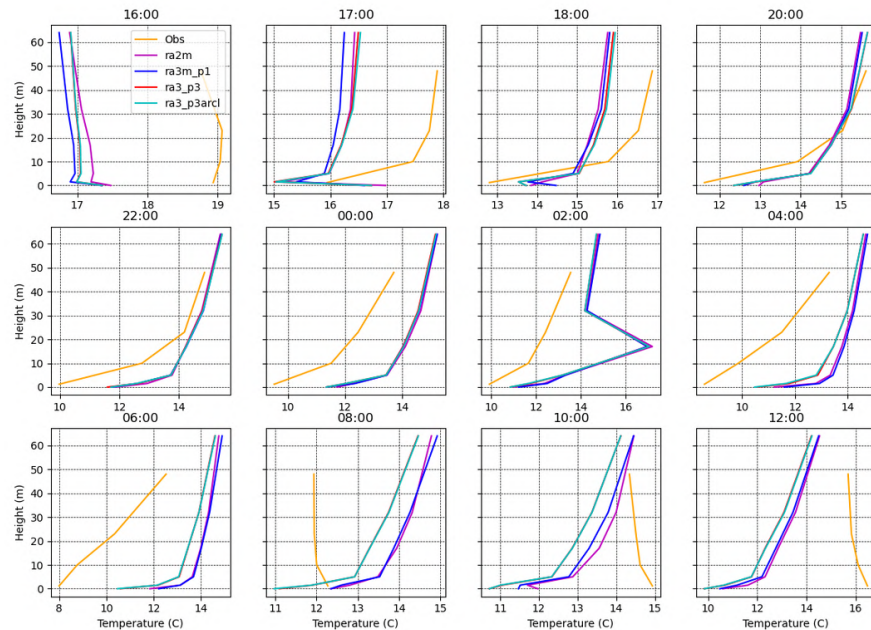

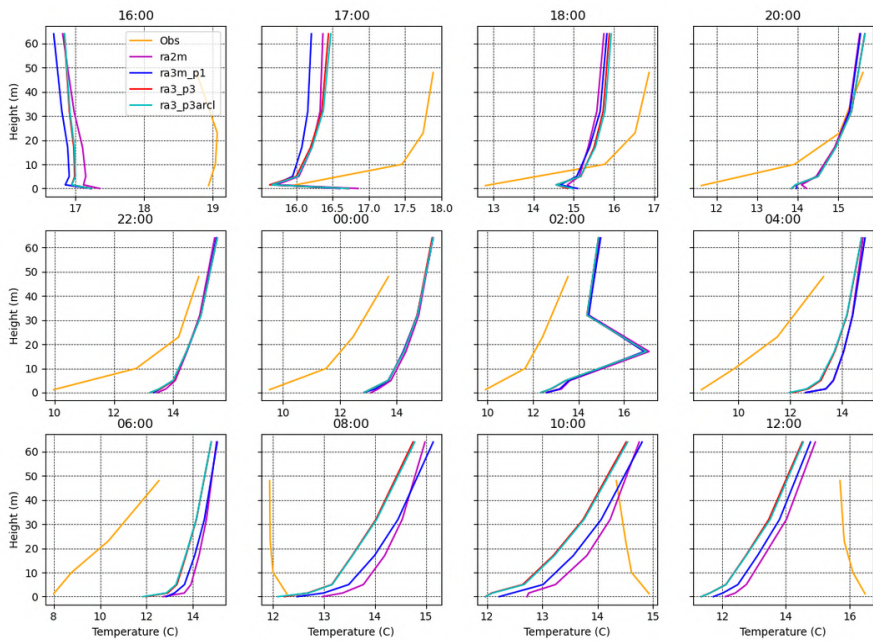

# Soil Heat Flux – ra3\_p3arcl and obs only – before and after change of set-up parameter

# Temperature Profiles – 28th to 29th October 2019 radiation fog case

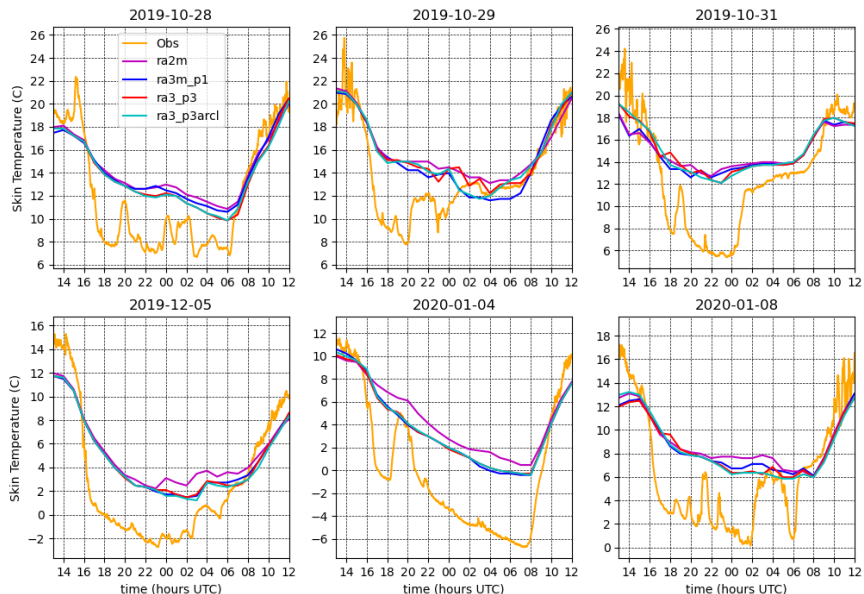

Le Couye – before change in set-up

Le Couye – after change in set-up
